

HIGH PERFORMANCE UNIVERSAL DRIVESHAFTS

- **Torque capacity upto 270,000 Nm**
- **Long Slip Movement versions**
- **Wide Angle versions upto 35°**
- **Flange sizes upto ø 435 mm**
- **Shafts upto 5000mm long**
- **DIN & SAE Flange fittings**
- **Quick release versions**
- **Multiple Shaft Systems**
- **Companion Flanges**
- **Flexible Couplings**
- **Mechanics Joints**
- **Universal Joints**
- **Double Joints**
- **Jack Shafts**

NDE Clarke Transmissions Ltd - Company Profile

NDE Clarke Transmissions manufacture high quality Driveshafts and drivelines to most configurations and specifications with either S.A.E. or D.I.N. standard Flanges for European and U.K. built equipment - including industrial applications.

NDE Clarke brings to the Driveshafts market a dynamic commercial approach, complementing substantial driveline skills, thereby producing a Cardan Shaft manufacturer which offers you the package of quality, price and service necessary to your business.

This technical manual defines our current standard programme and provides the technical information to assist the Design Engineer in the selection and layout of drivelines. It has not been possible to include a very wide range of special designs which we undertake within the contents of this manual. We would be pleased if you would contact our Technical Sales Department now for prompt technical assistance and pricing. NDE Clarke will offer you a complete engineering solution.

Universal Joint Theory

The Universal Joint also known as the Cardan or Hooke's Joint consists of a Journal (or spider) and four Bearings. Its purpose is to transmit torque from one inclined Shaft to another and the use of this construction can be traced back more than 700 years.

The uniform rotation ω_1 of a single Universal Joint deflected at a certain angle β will result in a non-uniform rotation of the output side of the Joint.

The non-constant velocity can be compensated by a second Joint provided that they are both in phase.

i.e. The Yokes (1) of the intermediate Shafts must be situated in the same plane. Marking arrows (2) must be noted.

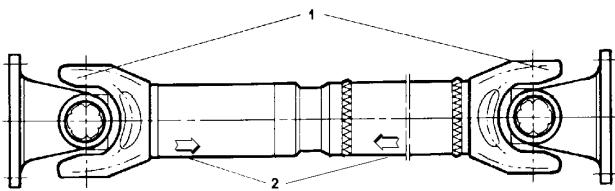

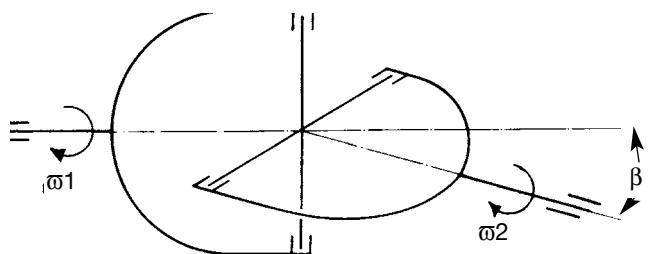

Diagram 1.

Shaft 1

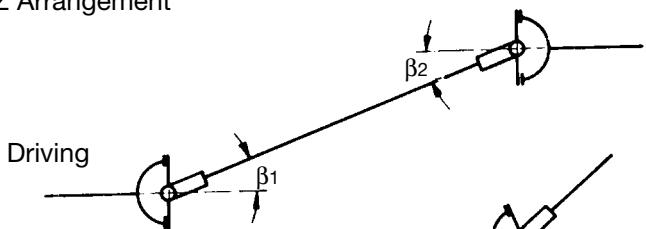

Shaft 2

This irregularity is called Cardan error and results in a sine like oscillation of the angular velocity ω_2 and a phase difference of Shaft 2 rotation angle ζ with the amplitude of plus or minus $\zeta_1 - \zeta_2$.

Diagram 2.

Z Arrangement

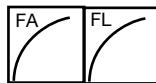

W Arrangement

The Joint angles β_1 and β_2 must be equal. Two common methods of achieving this are the W and Z arrangements.

How to select a Driveshaft

Selection of the correct Universal Driveshaft for an application is dependent on the service life required, this is based on the following criteria.

Step 1	Calculate torque using formula. $T = 9545 \times P \text{ (Nm)}$ n	Page 3
Step 2	Use life and angle requirements in conjunction with diagrams to determine Angle Factor (FA) and Life Factor (FL).	 Page 3
Step 3	Using formula determine corrected torque and make provisional selection using diagram.	$TC = T \times FA \times FL \text{ (Nm)}$ Page 3  Page 4
Step 4	Using table determine the service factor K which is dependent upon application.	e.g. Service Factor K Paper machines 2 Page 5
Step 5	Using formula determine maximum torque .	$T_{max} = T \times K \text{ (Nm)}$ Page 5
Step 6	Using the range data tables on pages 9-26, check T_{max} does not exceed the short duration torque (Tsd) for the selected series of Driveshaft.	 Page 9 to 26
Step 7	Check angle to speed relationship for the series selected as shown on diagram. Angle and speed must intersect below the series line.	 Page 6
Step 8	Check to ensure that the working angle does not exceed maximum stated angle for the series selected using the range data tables (note: compound angles must be calculated using formula). Again the resultant angle must not exceed the maximum angle stated.	 $\tan \beta = \sqrt{\tan^2 \beta H + \tan^2 \beta V}$ Page 6
Step 9	Check critical speed of the selected series does not exceed that in diagram. For Driveshafts with non-standard Tube dimensions, determine critical speed using formula.	 $n(\text{crit}) = 1.22 \times 10^7 \times \sqrt{\frac{D^2 + d^2}{L^2}} \text{ (r.p.m.)}$ Page 7

Driveshaft Selection

Selection of the correct Driveshaft for an application is dependent on the service life required which is based on the following criteria.

- 1) Torque
- 2) Joint Angles
- 3) Joint Life
- 4) Application Data; e.g. Shocks, Vibration, Cycle
- 5) Critical Speed

TORQUE

Torque is calculated using formula:

$$T = \frac{9545 \times P \text{ (Nm)}}{n}$$

Where

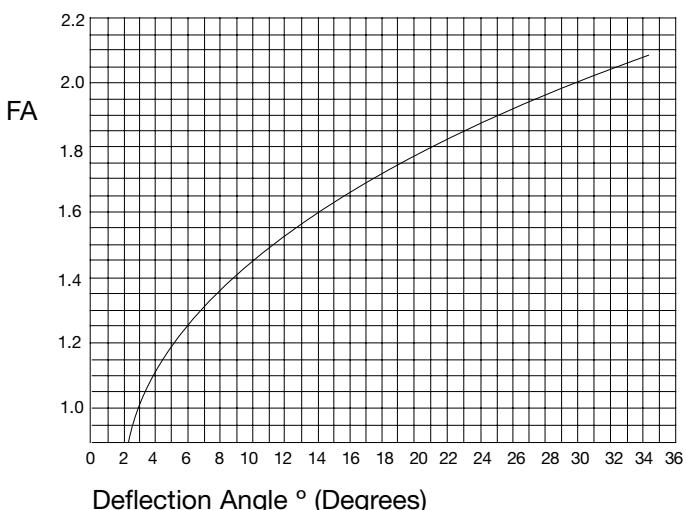

T = Torque in Nm

P = Power in kW (1 hp = 0.7457 kW)

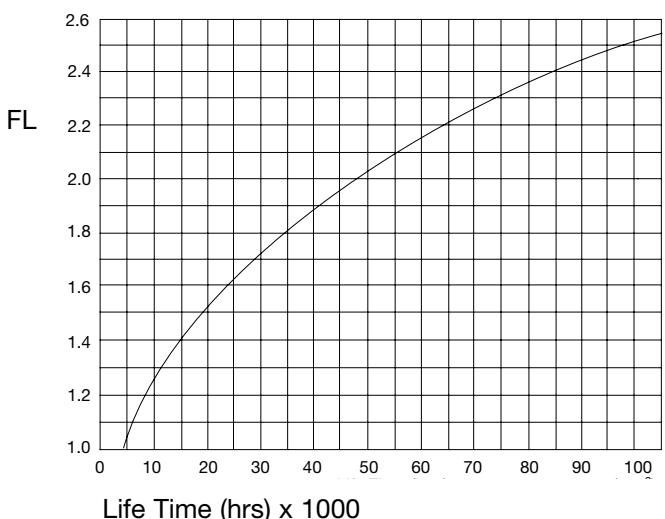

n = Speed in rpm

ANGLE AND LIFE FACTOR

Angle Factor

Life Factor

CORRECTED TORQUE

Corrected torque is calculated using formula:

$$TC = T \times FA \times FL \text{ (Nm)}$$

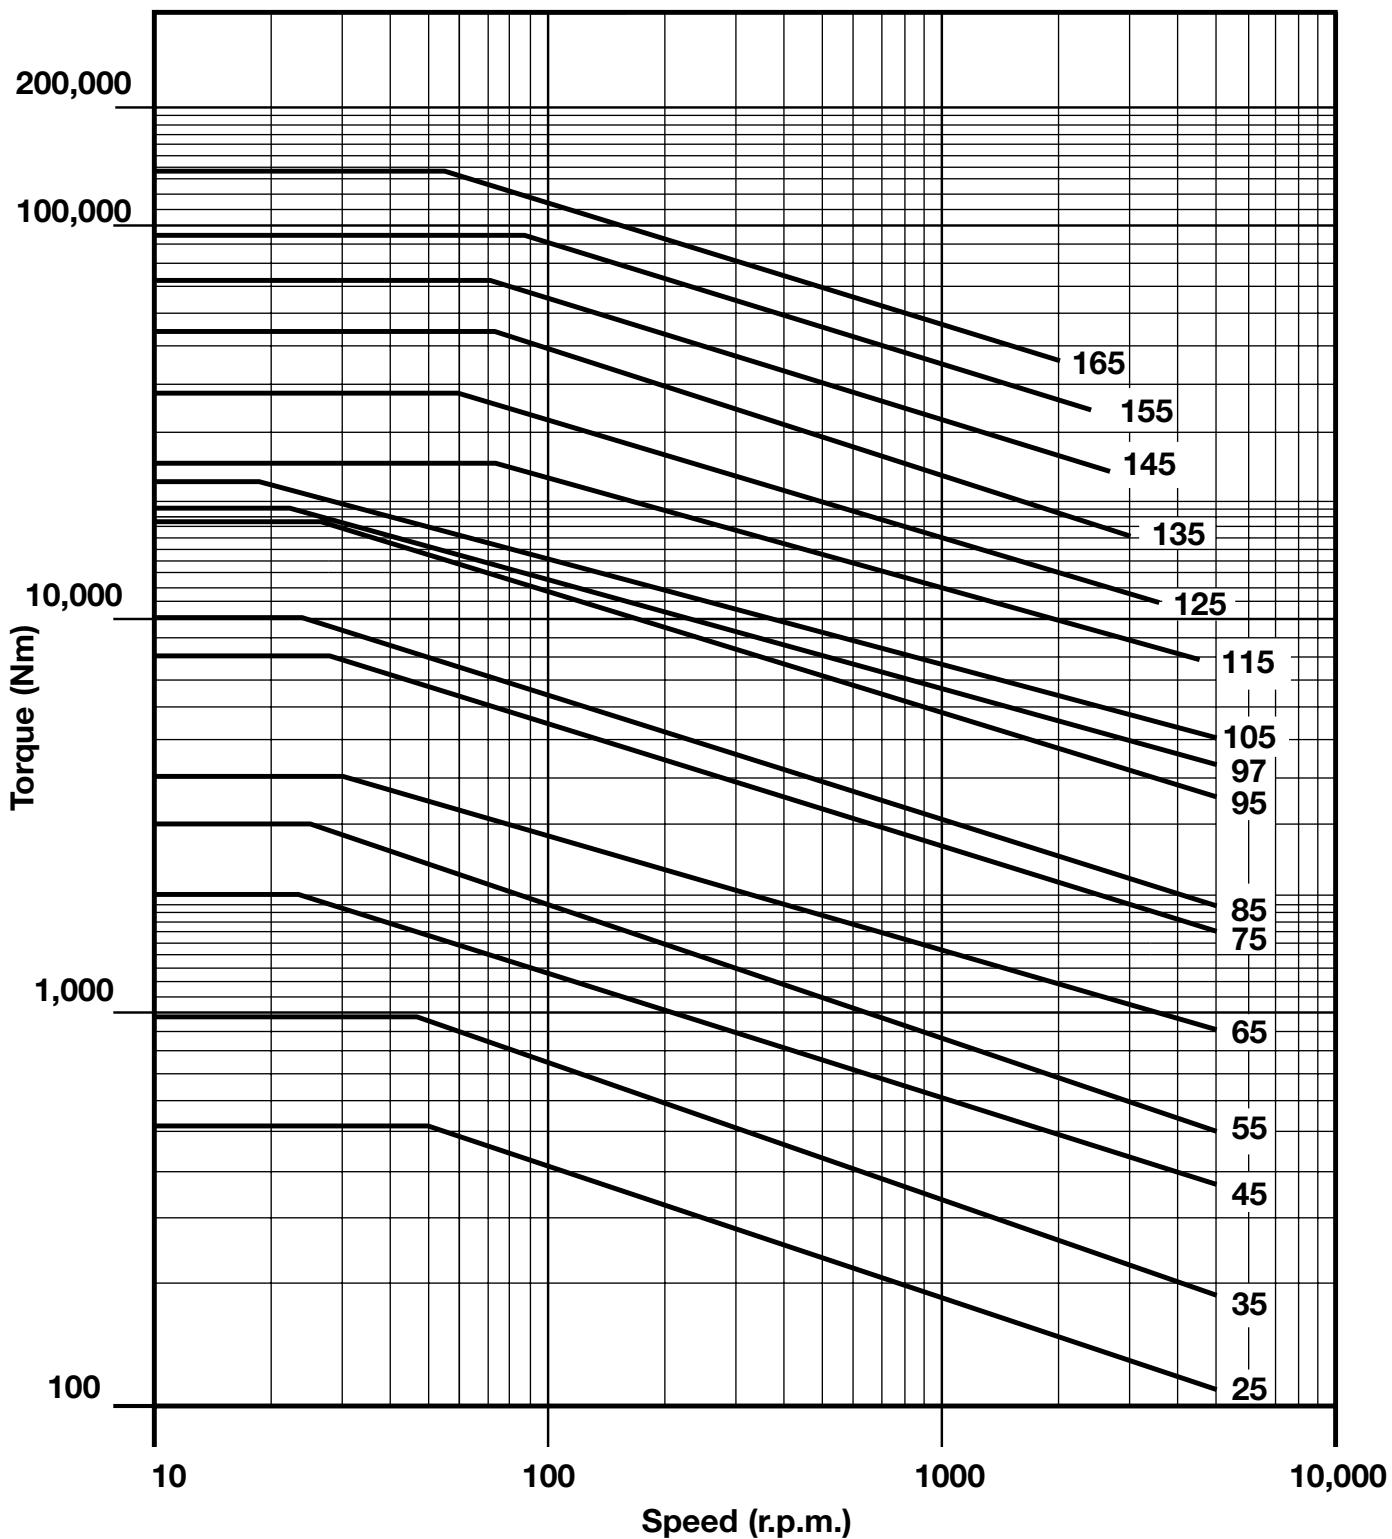

Where

TC = Corrected torque

T = Torque

FA = Angle factor

FL = Life Factor

PROVISIONAL SELECTIONStandard Joint life calculation graph based on operation for **5000 hours at 3°**.

Driveshaft Selection

SERVICE FACTOR K

Load condition Driven machine	Service factor K	Load condition Driven Machine	Service factor K
Continuous load	1,2 - 1,5	Heavy shock load	3
Centrifugal Pumps		Compressors (single cylinder)	
Generators (continuous)		Pumps (single cylinder)	
Conveyors (continuous)		Mixers	
Small Ventilators		Crane Travel Drives	
Light shock load	1,5 - 2	Bucket Wheel Reclaimers	
Diesel Engines		Presses	
Petrol Engines		Rotary Drilling Machines	
Centrifugal Pumps		Locomotive Secondary Drives	
Generators (not continuous)		Continuous Working Roller Tables	
Conveyors (not continuous)		Medium Section Mills	
Medium Ventilators		Continuous Slabbing and Blooming Mills	
Machine Tools		Continuous Heavy Tube Mills	
Printing Machines		Extreme shock load	4 - 6
Wood Handling Machines		Breast Roller Drives	
Small Paper and Textile Machines		Wrapper Roll Drives	
Medium shock load	2,5	Reversing Working Tables	
Pumps (multi cylinder)		Reversing Slabbing and Blooming Mills	
Compressors (multi cylinder)		Scale Breakers	
Large Ventilators		Vibration Conveyors	
Marine Transmissions			
Calendars			
Transport Roller Tables			
Rod and Bar Mills			
Small Pinch Rolls			
Small Tube Mills			
Locomotive Primary Drives			
Heavy Paper and Textile Machines			

MAXIMUM TORQUE

Shock and vibrations are dependant on the application. These must be taken into consideration by using Service Factor K when calculating the maximum torque.

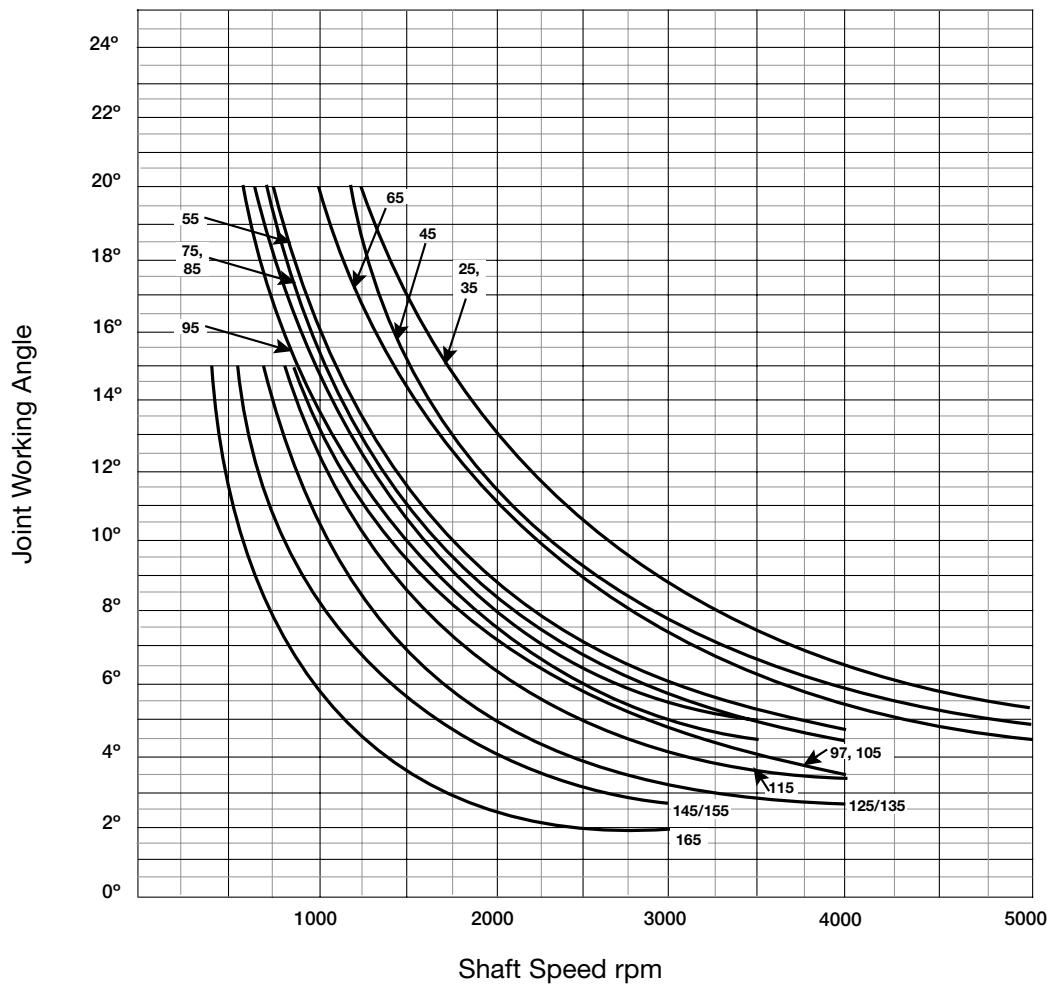

Maximum torque is calculated by using formula: $T_{max} = T \times K \text{ (Nm)}$

Where T_{max} = maximum torque
 T = Torque
 K = Service factor

Maximum torque calculated by this method should not exceed the short duration torque rating (T_{sd}) of the selected Driveshaft series i.e. $T_{max} \leq T_{sd}$ (short duration torque). The short duration torque capacity is used as the 'rating' of the Driveshafts.

ANGLE TO SPEED RELATIONSHIP

Angle and speed are governed by a relationship for each Joint size as shown below. Angle and speed must intersect below the series line.

Angles are also governed by the maximum working angles as listed in the catalogue for each series - Flange combination.

COMPOUND ANGLES

To determine the compound Joint angle when a Driveshaft is deflected in the two planes (V vertical, H horizontal).

The compound Joint angle is calculated using formula: $\tan \beta = \sqrt{\tan^2 \beta H + \tan^2 \beta V}$

Where

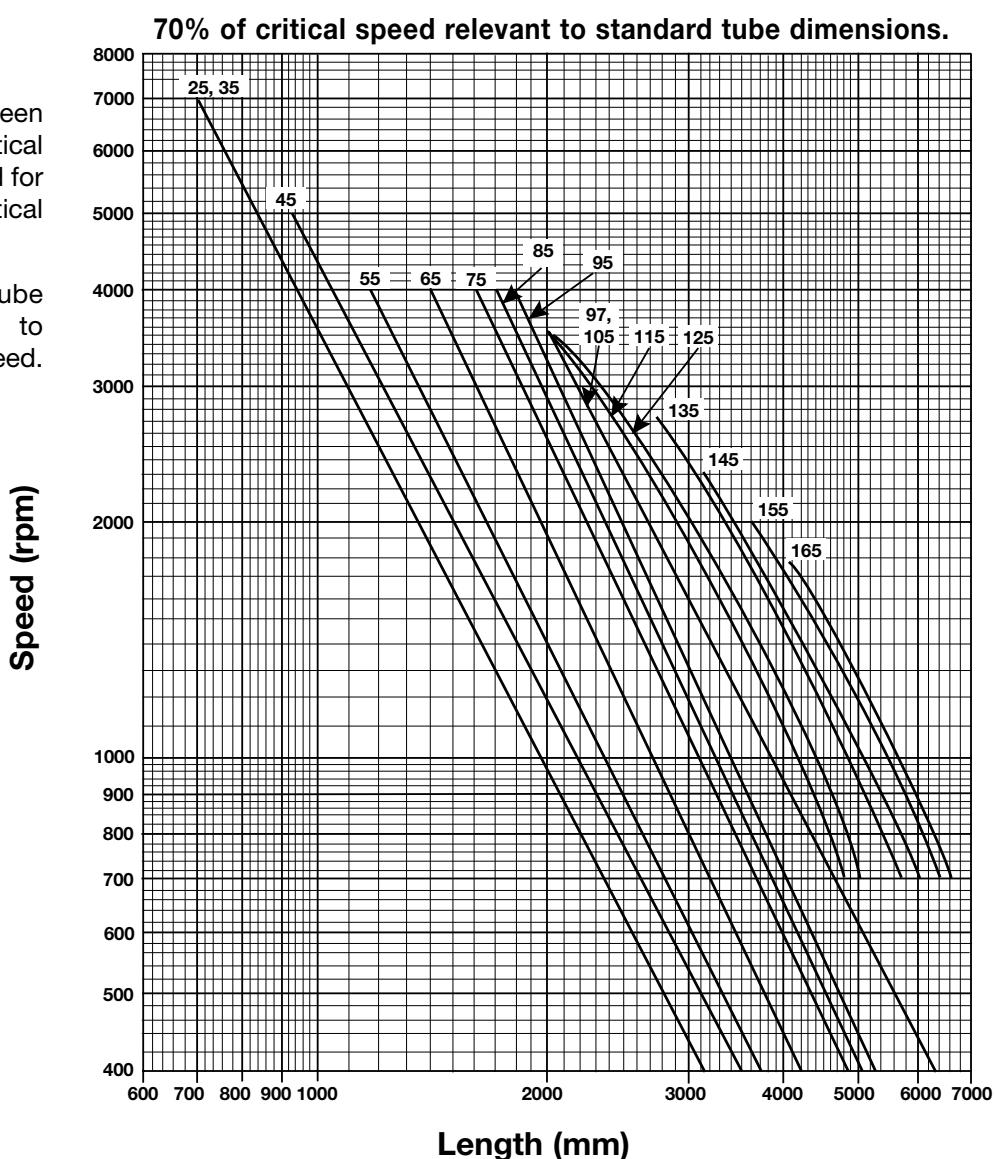

βH = Working angle horizontal plane

βV = Working angle vertical plane

CRITICAL SPEED

Another relationship is that between speed and length, referred to as critical speed. The maximum working speed for safety reasons is taken at 70% of critical speed relevant to tube dimensions.

For Driveshafts with **standard** tube dimensions use the graph shown to determine the maximum working speed.

For Driveshafts with **non-standard** tube dimensions

critical speed is calculated using formula :
$$n(\text{crit.}) = 1.22 \times 10^7 \times \frac{\sqrt{D^2 + d^2}}{L^2} \text{ (rpm)}$$

Where

n = Critical speed in rpm

D = Tube outside diameter (cm)

d = Tube inside diameter (cm)

L = Length of Driveshaft (cm)

Again the maximum working speed should be limited to 70% of the calculated critical speed.

CRITICAL LENGTH

Critical length can be calculated using formula :
$$L(\text{crit.}) = \frac{\sqrt{1.22 \times 10^7 \times \sqrt{D^2 + d^2}}}{n} \text{ (cm)}$$

J is given as the recommended distance from the Flange face to the centre line of the Support Bearing.
The Bearing can otherwise be located along the length M.

SPECIFICATION

NDE Clarke Driveshafts are supplied as complete units ready for installation into the vehicle or machine. They are balanced in accordance with Q(G) 16 VDI 2060, ISO 1940/41 and have a primer coat of paint.

Standard NDE Clarke Driveshafts are suitable for operation at ambient temperatures of -35° C to 60° C. Please contact us when using the Driveshafts in temperatures outside these conditions.

Before initial operation the Driveshaft must be greased using Lithium based grease with E.P. additives. The maximum greasing pressure is 15 bar.

TRANSPORTATION AND STORAGE

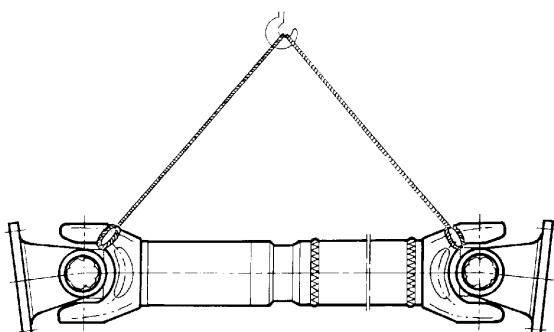

Since Driveshafts are manufactured as high quality products, they may suffer damage due to improper storage and transport, which could render them unusable.

The original NDE Clarke packing is only suitable for despatch and a short term storage. The Driveshafts should be stored in dry and weather protected areas. If the Driveshaft is to be stored for a long period, the Flange connecting faces should be treated with an anti-corrosion agent.

Transportation should be carried out with the Driveshafts in a horizontal position.

If the Driveshaft is put in any other position than horizontal, ***it is essential to prevent the spline elements from sliding apart***. This, and the tilting of the joints may cause personal injuries. Any impact must be avoided.

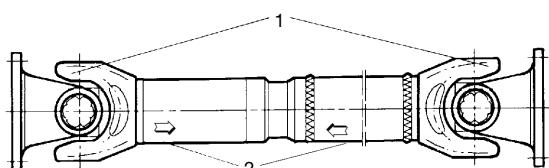

For the transportation of the Driveshafts we recommend the use of nylon ropes. The following sketch indicates a reasonable method.

INSTALLATION

For the installation of the Driveshafts, the following instructions must be observed:

- Check before immediate installation for possible transit damage.
- Driveshafts which have been stored for a long time should be regreased in working conditions before they are put into operation.
- When spray painting the Driveshafts, make sure that the area in which the Spline or the Seal glides is protected from paint.
- The faces of the Flanges must be free from anti-corrosion agents, paint, grease and dirt.
- Do not rotate the Driveshaft with assembly levers in the Joint because this may cause damage to the Joints, Grease Nipples or Air Relief Valves, where fitted.
- Nuts and Bolts of the correct size should be evenly tightened crosswise all round until securely locked to the recommended torque value. The Bolts should only be slightly oiled. Lubricants containing MOS_2 additives or similar must not be used.
- Check the position of the Yokes (1) according to drawing and ensure arrows are in line (2). See below.

- Before initial operation the Driveshaft must be greased using Lithium based grease with E.P. additives. The maximum greasing pressure is 15 bar.
- Connecting Flanges must be checked for concentricity, radial runout and fit to Shafts.

IMPORTANT

Guards - Rotating Shafts and Joints must be guarded to eliminate the possibility of physical contact or entanglement of clothing. It should be of rigid construction and firmly secured.

INSPECTION AND MAINTENANCE

Driveshaft inspection should be carried out at regular intervals and it would be reasonable to co-ordinate this with the maintenance work on other Vehicle parts. The maintenance intervals mentioned in the following section are only recommendations because maintenance intervals generally depend on the operating conditions of the Vehicle and on practical experience.

Driveshafts are used in a great variety of Industrial plants with very different operating conditions. We recommend inspections at regular intervals and, if possible, coordinate it with maintenance work on other parts of the equipment. However maintenance work should be carried out once a year at least.

- Check the Flange Bolts for tightness and retighten them with the prescribed torque. If they need replacing, Nuts and Bolts of the correct size should be evenly tightened crosswise all round until securely locked to the recommended torque value. The Bolts should only be slightly oiled. Lubricants containing MOS_2 additives or similar must not be used.
- Check lubrication schedule is being maintained.
- Backlash inspection. By lifting the Driveshaft check the Joint and the length compensation for visible or tangible backlash. If there is any perceptible play, the Driveshaft must be repaired.
- Check the Driveshaft for any unusual noise, vibration or abnormal behaviour and repair the damage, if any.

BOLTING

All inspections must include the checking of the Bolts for the prescribed tightening torques.

The Bolts should only be slightly oiled. Lubricants containing MOS_2 additives or similar must NOT be used.

LUBRICATION

The Driveshaft should be greased with a Lithium based Grease with EP additives.

Grease Nipples must be cleaned before greasing.

The maximum greasing pressure is 15 bar.

There are three greasing areas on the Driveshaft, the Universal Joints and the Splined Sleeve.

IMPORTANT

When lubricating Universal Joints, ensure that fresh Grease exudes from all four Bearing Seals to be certain that all Bearings have fresh Grease. The lubrication of the Splined Sleeve should be carried out with the Driveshaft fully compressed to prevent excessive axial force developing.

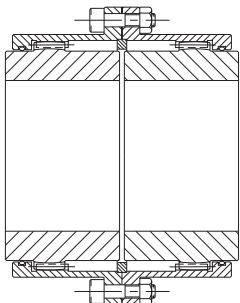

RE-GREASING INTERVALS

Recommended regreasing intervals (unless otherwise specified by the manufacturer of the Vehicle). The following maintenance intervals refer to European and comparable conditions. Other conditions may require shorter re-lubrication intervals.

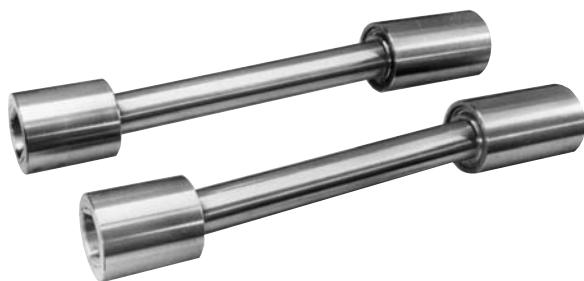

LUBRICATION PROGRAMME (Vehicles)	JOINTS & SLIDING SPLINES
Commercial Vehicles, Buses on road & similarly applied Vehicles	10,000 km or 3 months
Commercial Vehicles for on & off road use & similarly applied Vehicles	5,000 km or 2 months
Commercial & Construction Vehicles, Earth moving equipment, Tractors etc. & similarly applied Vehicles	2,500 km or 1 month

The recommended lubrication interval for Driveshafts used in Industrial plants in normal operating conditions is three months. Unfavourable effects like temperature, dirt and water may necessitate shorter lubricating intervals. We recommend adapting the lubricating intervals to the individual operating conditions.
